Summary
A classifier is an algorithm that assigns a class from a predefined set to a case or object, based on the values of descriptive attributes.

An optimal classifier maximizes the probability of a correct class assignment.

Let $C$ be a class attribute with $\text{dom}(C) = \{c_1, \ldots, c_{n_C}\}$, which occur with probabilities $p_i$, $1 \leq i \leq n_C$.

Let $q_i$ be the probability with which a classifier assigns class $c_i$. ($q_i \in \{0, 1\}$ for a deterministic classifier)

The probability of a correct assignment is

$$P(\text{correct assignment}) = \sum_{i=1}^{n_C} p_i q_i.$$

Therefore the best choice for the $q_i$ is

$$q_i = \begin{cases} 1, & \text{if } p_i = \max_{k=1}^{n_C} p_k, \\ 0, & \text{otherwise}. \end{cases}$$
Consequence: An optimal classifier should assign the most probable class.

This argument does not change if we take descriptive attributes into account.

Let $U = \{A_1, \ldots, A_m\}$ be a set of descriptive attributes with domains $\text{dom}(A_k)$, $1 \leq k \leq m$.

Let $A_1 = a_1, \ldots, A_m = a_m$ be an instantiation of the descriptive attributes.

An optimal classifier should assign the class $c_i$ for which

$$P(C = c_i \mid A_1 = a_1, \ldots, A_m = a_m) = \max_{j=1}^{n_C} P(C = c_j \mid A_1 = a_1, \ldots, A_m = a_m)$$

**Problem:** We cannot store a class (or the class probabilities) for every possible instantiation $A_1 = a_1, \ldots, A_m = a_m$ of the descriptive attributes. (The table size grows exponentially with the number of attributes.)

Therefore: **Simplifying assumptions are necessary.**
Bayes’ rule is a formula that can be used to “invert” conditional probabilities: Let $A$ and $B$ be events, $P(A) > 0$. Then

$$P(B \mid A) = \frac{P(A \mid B) \cdot P(B)}{P(A)}.$$ 

Bayes’ rule follows directly from the definition of conditional probability:

$$P(B \mid A) = \frac{P(A \cap B)}{P(A)} \quad \text{and} \quad P(A \mid B) = \frac{P(A \cap B)}{P(B)}.$$

Bayes’ classifiers: Compute the class probabilities as

$$P(C = c_i \mid A_1 = a_1, \ldots, A_m = a_m) = \frac{P(A_1 = a_1, \ldots, A_m = a_m \mid C = c_i) \cdot P(C = c_i)}{P(A_1 = a_1, \ldots, A_m = a_m)}.$$ 

Looks unreasonable at first sight: Even more probabilities to store.
Naive Bayes Classifiers

Naive Assumption:
The descriptive attributes are conditionally independent given the class.

Bayes’ Rule:
\[
P(C = c_i \mid \vec{A}) = \frac{P(A_1 = a_1, \ldots, A_m = a_m \mid C = c_i) \cdot P(C = c_i)}{P(A_1 = a_1, \ldots, A_m = a_m)} \leftarrow p_0
\]

\[
P(\vec{A}) = P(A_1 = a_1, \ldots, A_m = a_m) = p_0 \text{ used as abbrev., normalizing constant.}
\]

Chain Rule of Probability:
\[
P(C = c_i \mid \vec{A}) = \frac{P(C = c_i)}{p_0} \cdot \prod_{k=1}^{m} P(A_k = a_k \mid A_1 = a_1, \ldots, A_{k-1} = a_{k-1}, C = c_i)
\]

Conditional Independence Assumption:
\[
P(C = c_i \mid \vec{A}) = \frac{P(C = c_i)}{p_0} \cdot \prod_{k=1}^{m} P(A_k = a_k \mid C = c_i)
\]
Based on the **product rule** of probability:

\[ P(A \land B) = P(A \mid B) \cdot P(B) \]

(Multiply definition of conditional probability with \( P(B) \).)

**Multiple application** of the product rule yields:

\[
P(A_1, \ldots, A_m) = P(A_m \mid A_1, \ldots, A_{m-1}) \cdot P(A_1, \ldots, A_{m-1})
\]

\[
= P(A_m \mid A_1, \ldots, A_{m-1})
\]

\[
\cdot P(A_{m-1} \mid A_1, \ldots, A_{m-2}) \cdot P(A_1, \ldots, A_{m-2})
\]

\[
= \vdots
\]

\[
= \prod_{k=1}^{m} P(A_k \mid A_1, \ldots, A_{k-1})
\]

The scheme works also if there is already a condition in the original expression:

\[
P(A_1, \ldots, A_m \mid C) = \prod_{i=1}^{m} P(A_k \mid A_1, \ldots, A_{k-1}, C)
\]
Reminder: **stochastic independence** (unconditional)

\[
P(A \land B) = P(A) \cdot P(B)
\]

(Joint probability is the product of the individual probabilities.)

Comparison to the **product rule**

\[
P(A \land B) = P(A | B) \cdot P(B)
\]

shows that this is equivalent to

\[
P(A | B) = P(A)
\]

The same formulae hold conditionally, i.e.

\[
P(A \land B | C) = P(A | C) \cdot P(B | C)
\]

and

\[
\]

**Conditional independence allows us to cancel some conditions.**
Conditional Independence: An Example

(Weak) Dependence in the entire dataset: \(X\) and \(Y\) dependent.
No Dependence in Group 1: $X$ and $Y$ conditionally independent given Group 1.
No Dependence in Group 2: $X$ and $Y$ conditionally independent given Group 2.
Consequence: Manageable amount of data to store.
Store distributions $P(C = c_i)$ and $\forall 1 \leq k \leq m : P(A_k = a_k \mid C = c_i)$.

It is not necessary to compute $p_0$ explicitly, because it can be computed implicitly by normalizing the computed values to sum 1.

Estimation of Probabilities:

Nominal/Symbolic Attributes

$$\hat{P}(A_k = a_k \mid C = c_i) = \frac{\#(A_k = a_k, C = c_i) + \gamma}{\#(C = c_i) + n_{A_k}\gamma}$$

$\#(A = a, C = c)$ counts, how many data with this specific attribute combination exist in the data set.

$\gamma$ is called **Laplace correction**: Assume for every class $c_i$ some number of hypothetical samples for every value of $A_k$ to prevent the estimate to be 0 if $\#(A_k = a_k, C = c_i) = 0$.

$\gamma = 0$: Maximum likelihood estimation. Common choices: $\gamma = 1$ or $\gamma = \frac{1}{2}$. 
Estimation of Probabilities:

**Metric/Numeric Attributes:** Assume a normal distribution.

\[
P(A_k = a_k \mid C = c_i) = \frac{1}{\sqrt{2\pi \sigma_k(c_i)}} \exp \left( -\frac{(a_k - \mu_k(c_i))^2}{2\sigma_k^2(c_i)} \right)
\]

Estimate of mean value

\[
\hat{\mu}_k(c_i) = \frac{1}{\#(C = c_i)} \sum_{j=1}^{\#(C=c_i)} a_k(j)
\]

Estimate of variance

\[
\hat{\sigma}_k^2(c_i) = \frac{1}{\xi} \sum_{j=1}^{\#(C=c_i)} (a_k(j) - \hat{\mu}_k(c_i))^2
\]

\[
\xi = \#(C = c_i) : \text{Maximum likelihood estimation}
\]

\[
\xi = \#(C = c_i) - 1: \text{Unbiased estimation}
\]

A simple database and estimated (conditional) probability distributions.
Naive Bayes Classifiers: Simple Example 1

\[ P(\text{Drug A} \mid \text{male, 61, normal}) \]
\[ = c_1 \cdot P(\text{Drug A}) \cdot P(\text{male} \mid \text{Drug A}) \cdot P(61 \mid \text{Drug A}) \cdot P(\text{normal} \mid \text{Drug A}) \]
\[ \approx c_1 \cdot 0.5 \cdot 0.5 \cdot 0.004787 \cdot 0.5 = c_1 \cdot 5.984 \cdot 10^{-4} = 0.219 \]

\[ P(\text{Drug B} \mid \text{male, 61, normal}) \]
\[ = c_1 \cdot P(\text{Drug B}) \cdot P(\text{male} \mid \text{Drug B}) \cdot P(61 \mid \text{Drug B}) \cdot P(\text{normal} \mid \text{Drug B}) \]
\[ \approx c_1 \cdot 0.5 \cdot 0.5 \cdot 0.017120 \cdot 0.5 = c_1 \cdot 2.140 \cdot 10^{-3} = 0.781 \]

\[ P(\text{Drug A} \mid \text{female, 30, normal}) \]
\[ = c_2 \cdot P(\text{Drug A}) \cdot P(\text{female} \mid \text{Drug A}) \cdot P(30 \mid \text{Drug A}) \cdot P(\text{normal} \mid \text{Drug A}) \]
\[ \approx c_2 \cdot 0.5 \cdot 0.5 \cdot 0.027703 \cdot 0.5 = c_2 \cdot 3.471 \cdot 10^{-3} = 0.671 \]

\[ P(\text{Drug B} \mid \text{female, 30, normal}) \]
\[ = c_2 \cdot P(\text{Drug B}) \cdot P(\text{female} \mid \text{Drug B}) \cdot P(30 \mid \text{Drug B}) \cdot P(\text{normal} \mid \text{Drug B}) \]
\[ \approx c_2 \cdot 0.5 \cdot 0.5 \cdot 0.013567 \cdot 0.5 = c_2 \cdot 1.696 \cdot 10^{-3} = 0.329 \]
100 data points, 2 classes

Classes overlap: classification is not perfect
Naive Bayes Classifiers: Simple Example 3

20 data points, 2 classes

Small squares: mean values

Inner ellipses:
one standard deviation

Outer ellipses:
two standard deviations

Attributes are not conditionally independent given the class

Naive Bayes Classifier
150 data points, 3 classes
Iris setosa  (red)
Iris versicolor  (green)
Iris virginica  (blue)

Shown: 2 out of 4 attributes
sepal length
sepal width
petal length  (horizontal)
petal width  (vertical)

6 misclassifications
on the training data
(with all 4 attributes)
Restricted to metric/numeric attributes (only the class is nominal/symbolic).

**Simplifying Assumption:** Each class can be described by a multivariate normal distribution.

\[
f(A_1 = a_1, \ldots, A_m = a_m \mid C = c_i) = \frac{1}{\sqrt{(2\pi)^m |\Sigma_i|}} \exp \left( -\frac{1}{2} (\vec{a} - \vec{\mu}_i)^\top \Sigma_i^{-1} (\vec{a} - \vec{\mu}_i) \right)
\]

- \(\vec{\mu}_i\): mean value vector for class \(c_i\)
- \(\Sigma_i\): covariance matrix for class \(c_i\)

Intuitively: Each class has a bell-shaped probability density.

Naive Bayes classifiers: Covariance matrices are diagonal matrices. (Details about this relation are given below.)
Full Bayes Classifiers

Estimation of Probabilities:

Estimate of mean value vector

\[ \hat{\mu}_i = \frac{1}{\#(C = c_i)} \sum_{j=1}^{\#(C = c_i)} \bar{a}(j) \]

Estimate of covariance matrix

\[ \hat{\Sigma}_i = \frac{1}{\xi} \sum_{j=1}^{\#(C = c_i)} \left( \bar{a}(j) - \hat{\mu}_i \right) \left( \bar{a}(j) - \hat{\mu}_i \right)^\top \]

\[ \xi = \#(C = c_i) \quad : \text{Maximum likelihood estimation} \]
\[ \xi = \#(C = c_i) - 1 \quad : \text{Unbiased estimation} \]

\( \bar{x}^\top \) denotes the transpose of the vector \( \bar{x} \).

\( \bar{x}\bar{x}^\top \) is the so-called **outer product** or **matrix product** of \( \bar{x} \) with itself.
Comparison of Naive and Full Bayes Classifiers

Naive Bayes classifiers for metric/numeric data are equivalent to full Bayes classifiers with diagonal covariance matrices:

\[
f(A_1 = a_1, \ldots, A_m = a_m | C = c_i) = \frac{1}{\sqrt{(2\pi)^m |\Sigma_i|}} \cdot \exp\left(-\frac{1}{2} (\vec{a} - \vec{\mu}_i)^\top \Sigma_i^{-1} (\vec{a} - \vec{\mu}_i)\right)
\]

\[
= \frac{1}{\sqrt{(2\pi)^m \prod_{k=1}^{m} \sigma_{i,k}^2}} \cdot \exp\left(-\frac{1}{2} (\vec{a} - \vec{\mu}_i)^\top \text{diag}(\sigma_{i,1}^{-2}, \ldots, \sigma_{i,m}^{-2}) (\vec{a} - \vec{\mu}_i)\right)
\]

\[
= \frac{1}{\prod_{k=1}^{m} \sqrt{2\pi \sigma_{i,k}^2}} \cdot \exp\left(-\frac{1}{2} \sum_{k=1}^{m} \frac{(a_k - \mu_{i,k})^2}{\sigma_{i,k}^2}\right)
\]

\[
= \prod_{k=1}^{m} \frac{1}{\sqrt{2\pi \sigma_{i,k}^2}} \cdot \exp\left(-\frac{(a_k - \mu_{i,k})^2}{2\sigma_{i,k}^2}\right) \cong \prod_{k=1}^{m} f(A_k = a_k | C = c_i),
\]

where \(f(A_k = a_k | C = c_i)\) are the density functions used by a naive Bayes classifier.
Comparison of Naive and Full Bayes Classifiers

Naive Bayes Classifier

Full Bayes Classifier
Full Bayes Classifiers: Iris Data

150 data points, 3 classes
- Iris setosa  (red)
- Iris versicolor (green)

Summary
Assignment of a drug to a patient:

A Very Simple Decision Tree

Blood pressure

- high → Drug A
- low → Drug B
  - normal
  - Age
    - ≤ 40 → Drug A
    - > 40 → Drug B
Recursive Descent:

Start at the root node.

If the current node is an leaf node:
   Return the class assigned to the node.

If the current node is an inner node:
   Test the attribute associated with the node.
   Follow the branch labeled with the outcome of the test.
   Apply the algorithm recursively.

Intuitively: Follow the path corresponding to the case to be classified.
Assignment of a drug to a patient:

Blood pressure

- high: Drug A
- normal: Age
  - ≤ 40: Drug A
  - > 40: Drug B
- low: Drug B
Assignment of a drug to a patient:

Blood pressure
  \[\text{normal}\]
  \[\text{high}\]
  \[\text{low}\]
  \[\text{Age}\]
  \[\leq 40\]
  \[> 40\]

Drug A

Drug B
Assignment of a drug to a patient:

- **Blood pressure**: high, normal, low
  - **Age**: ≤ 40, > 40
    - ≤ 40: Drug A
    - > 40: Drug B
Induction of Decision Trees

**Top-down approach**
- Build the decision tree from top to bottom (from the root to the leaves).

**Greedy Selection of a Test Attribute**
- Compute an evaluation measure for all attributes.
- Select the attribute with the best evaluation.

**Divide and Conquer / Recursive Descent**
- Divide the example cases according to the values of the test attribute.
- Apply the procedure recursively to the subsets.
- Terminate the recursion if
  - all cases belong to the same class
  - no more test attributes are available
Induction of a Decision Tree: Example

Patient database

12 example cases
3 descriptive attributes
1 class attribute

Assignment of drug
(without patient attributes)
always drug A or always drug B:
50% correct (in 6 of 12 cases)

Total: 100% correct (6 of 6)
Assignment of a drug to a patient:

- Blood pressure:
  - high: Drug A
  - normal: Age
    - ≤ 40: Drug A
    - > 40: Drug B
  - low: Drug B
Decision Tree Induction: Notation

\( S \)  
a set of case or object descriptions

\( C \)  
the class attribute

\( A^{(1)}, \ldots, A^{(m)} \)  
other attributes (index dropped in the following)

\( \text{dom}(C) = \{c_1, \ldots, c_{n_C}\} \),  
\( n_C \): number of classes

\( \text{dom}(A) = \{a_1, \ldots, a_{n_A}\} \),  
\( n_A \): number of attribute values

\( N_\cdot \)  
total number of case or object descriptions i.e. \( N_\cdot = |S| \)

\( N_i. \)  
absolute frequency of the class \( c_i \)

\( N_{.j} \)  
absolute frequency of the attribute value \( a_j \)

\( N_{ij} \)  
absolute frequency of the combination of the class \( c_i \) and the attribute value \( a_j \). It is \( N_i. = \sum_{j=1}^{n_A} N_{ij} \) and \( N_{.j} = \sum_{i=1}^{n_C} N_{ij} \).

\( p_i. \)  
relative frequency of the class \( c_i \), \( p_i. = \frac{N_i.}{N_\cdot} \)

\( p_{.j} \)  
relative frequency of the attribute value \( a_j \), \( p_{.j} = \frac{N_{.j}}{N_\cdot} \)

\( p_{ij} \)  
relative frequency of the combination of class \( c_i \) and attribute value \( a_j \), \( p_{ij} = \frac{N_{ij}}{N_\cdot} \)

\( p_{i|j} \)  
relative frequency of the class \( c_i \) in cases having attribute value \( a_j \), \( p_{i|j} = \frac{N_{ij}}{N_{.j}} = \frac{p_{ij}}{p_{.j}} \)
function grow_tree ($S$: set of cases) : node;
begin

best_v := WORTHLESS;
for all untested attributes $A$ do
    compute frequencies $N_{ij}$, $N_{i.}$, $N_{.j}$ for $1 \leq i \leq n_C$ and $1 \leq j \leq n_A$;
    compute value $v$ of an evaluation measure using $N_{ij}$, $N_{i.}$, $N_{.j}$;
    if $v > best_v$ then best_v := $v$; best_A := $A$; end;
end

if best_v = WORTHLESS then
    create leaf node $x$;
    assign majority class of $S$ to $x$;
else
    create test node $x$;
    assign test on attribute best_A to $x$;
    for all $a \in \text{dom}(best_A)$ do $x$.$\text{child}[a] := \text{grow_tree}(S|_{best_A=a})$; end;
end;
return $x$;
end;
Evaluation measure used in the above example:

**rate of correctly classified example cases.**

Advantage: simple to compute, easy to understand.

Disadvantage: works well only for two classes.

If there are more than two classes, the rate of misclassified example cases **neglects a lot of the available information.**

Only the majority class—that is, the class occurring most often in (a subset of) the example cases—is really considered.

The distribution of the other classes has no influence. However, a good choice here can be important for deeper levels of the decision tree.

**Therefore:** Study also other evaluation measures. Here:

**Information gain** and its various normalizations.

**$\chi^2$ measure** (well-known in statistics).
An Information-theoretic Evaluation Measure

**Information Gain**  (Kullback and Leibler 1951, Quinlan 1986)

Based on Shannon Entropy $H = - \sum_{i=1}^{n} p_i \log_2 p_i$  (Shannon 1948)

\[
I_{\text{gain}}(C, A) = H(C) - H(C|A)
\]

- $H(C)$: Entropy of the class distribution ($C$: class attribute)
- $H(C|A)$: *Expected entropy* of the class distribution if the value of the attribute $A$ becomes known
- $H(C) - H(C|A)$: Expected entropy reduction or *information gain*
Inducing the Decision Tree with Information Gain

Information gain for drug and sex:

\[
H(\text{Drug}) = -\left( \frac{1}{2} \log_2 \frac{1}{2} + \frac{1}{2} \log_2 \frac{1}{2} \right) = 1
\]

\[
H(\text{Drug} \mid \text{Sex}) = \frac{1}{2} \left( -\frac{1}{2} \log_2 \frac{1}{2} - \frac{1}{2} \log_2 \frac{1}{2} \right) + \frac{1}{2} \left( -\frac{1}{2} \log_2 \frac{1}{2} - \frac{1}{2} \log_2 \frac{1}{2} \right) = 1
\]

\[
I_{\text{gain}}(\text{Drug}, \text{Sex}) = 1 - 1 = 0
\]

No gain at all since the initial the uniform distribution of drug is splitted into two (still) uniform distributions.
Inducing the Decision Tree with Information Gain

Information gain for drug and age:

\[
H(\text{Drug}) = - \left( \frac{1}{2} \log_2 \frac{1}{2} + \frac{1}{2} \log_2 \frac{1}{2} \right) = 1
\]

\[
H(\text{Drug} \mid \text{Age}) = \frac{1}{2} \left( \frac{2}{3} \log_2 \frac{2}{3} - \frac{1}{3} \log_2 \frac{1}{3} \right) + \frac{1}{2} \left( \frac{1}{3} \log_2 \frac{1}{3} - \frac{2}{3} \log_2 \frac{2}{3} \right) \approx 0.9183
\]

\[
I_{\text{gain}}(\text{Drug}, \text{Age}) = 1 - 0.9183 = 0.0817
\]

Splitting w.r.t. age can reduce the overall entropy.
Information gain for drug and blood pressure:

\[ H(\text{Drug}) = -\left( \frac{1}{2} \log_2 \frac{1}{2} + \frac{1}{2} \log_2 \frac{1}{2} \right) = 1 \]

\[ H(\text{Drug} \mid \text{Blood\_pr}) = \frac{1}{4} \cdot 0 + \frac{1}{2} \left( -\frac{2}{3} \log_2 \frac{2}{3} - \frac{1}{3} \log_2 \frac{1}{3} \right) + \frac{1}{4} \cdot 0 = 0.5 \]

\[ I_{\text{gain}}(\text{Drug}, \text{Blood\_pr}) = 1 - 0.5 = 0.5 \]

Largest information gain, so we first split w. r. t. blood pressure (as in the example with misclassification rate).
Next level: Subtree blood pressure is normal.

Information gain for drug and sex:

\[ H(\text{Drug}) = - \left( \frac{1}{2} \log_2 \frac{1}{2} + \frac{1}{2} \log_2 \frac{1}{2} \right) = 1 \]

\[ H(\text{Drug} \mid \text{Sex}) = \frac{1}{2} \left( \frac{2}{3} \log_2 \frac{2}{3} - \frac{1}{3} \log_2 \frac{1}{3} \right) + \frac{1}{2} \left( \frac{1}{3} \log_2 \frac{1}{3} - \frac{2}{3} \log_2 \frac{2}{3} \right) = 0.9183 \]

\[ I_{\text{gain}}(\text{Drug}, \text{Sex}) = 0.0817 \]

Entropy can be decreased.
Next level: Subtree blood pressure is normal.

Information gain for drug and age:

\[
H(\text{Drug}) = - \left( \frac{1}{2} \log_2 \frac{1}{2} + \frac{1}{2} \log_2 \frac{1}{2} \right) = 1
\]

\[
H(\text{Drug} | \text{Age}) = \frac{1}{2} \cdot 0 + \frac{1}{2} \cdot 0 = 0
\]

\[
I_{\text{gain}}(\text{Drug}, \text{Age}) = 1
\]

Maximal information gain, that is we result in a perfect classification (again, as in the case of using misclassification rate).
Let $S = \{s_1, \ldots, s_n\}$ be a finite set of alternatives having positive probabilities $P(s_i), i = 1, \ldots, n$, satisfying $\sum_{i=1}^{n} P(s_i) = 1$.

**Shannon Entropy:**

$$H(S) = - \sum_{i=1}^{n} P(s_i) \log_2 P(s_i)$$

Intuitively: **Expected number of yes/no questions that have to be asked in order to determine the obtaining alternative.**

Suppose there is an oracle, which knows the obtaining alternative, but responds only if the question can be answered with “yes” or “no”.

A better question scheme than asking for one alternative after the other can easily be found: Divide the set into two subsets of about equal size.

Ask for containment in an arbitrarily chosen subset.

Apply this scheme recursively $\rightarrow$ number of questions bounded by $\lceil \log_2 n \rceil$. 
\[ P(s_1) = 0.10, \quad P(s_2) = 0.15, \quad P(s_3) = 0.16, \quad P(s_4) = 0.19, \quad P(s_5) = 0.40 \]

Shannon entropy: \[ -\sum_i P(s_i) \log_2 P(s_i) = 2.15 \text{ bit/symbol} \]

**Linear Traversal**

\[
\begin{array}{ccccc}
s_1, s_2, s_3, s_4, s_5 & & & & \\
\downarrow & & & & \\
s_2, s_3, s_4, s_5 & & & & \\
\downarrow & & & & \\
s_3, s_4, s_5 & & & & \\
\downarrow & & & & \\
s_4, s_5 & & & & \\
\downarrow & & & & \\
s_1 & 0.10 & s_2 & 0.15 & s_3 & 0.16 & s_4 & 0.19 & s_5 & 0.40 \\
1 & 2 & 3 & 4 & 4
\end{array}
\]

Code length: 3.24 bit/symbol
Code efficiency: 0.664

**Equal Size Subsets**

\[
\begin{array}{ccccc}
s_1, s_2, s_3, s_4, s_5 & & & & \\
\downarrow & & & & \\
s_1, s_2 & & & & \\
\downarrow & & & & \\
s_1 & 0.10 & s_2 & 0.15 & \\
1 & 2 & 2 & 3 & 3
\end{array}
\]

Code length: 2.59 bit/symbol
Code efficiency: 0.830
Splitting into subsets of about equal size can lead to a bad arrangement of the alternatives into subsets $\rightarrow$ high expected number of questions.

Good question schemes take the probability of the alternatives into account.

**Shannon-Fano Coding** (1948)

Build the question/coding scheme top-down.

Sort the alternatives w.r.t. their probabilities.

Split the set so that the subsets have about equal probability (splits must respect the probability order of the alternatives).

**Huffman Coding** (1952)

Build the question/coding scheme bottom-up.

Start with one element sets.

Always combine those two sets that have the smallest probabilities.
\[ P(s_1) = 0.10, \quad P(s_2) = 0.15, \quad P(s_3) = 0.16, \quad P(s_4) = 0.19, \quad P(s_5) = 0.40 \]

Shannon entropy: \(- \sum_i P(s_i) \log_2 P(s_i) = 2.15 \text{ bit/symbol}\)

**Shannon–Fano Coding** (1948)

```
\begin{array}{c}
\text{s}_1, \text{s}_2, \text{s}_3, \text{s}_4, \text{s}_5 \\
| \text{s}_1, \text{s}_2, \text{s}_3 \quad 0.41 \\
| \quad \text{s}_4, \text{s}_5 \quad 0.59 \\
\text{s}_1, \text{s}_2 \quad 0.25 \\
\text{s}_1 \quad 0.10 \\
\text{s}_2 \quad 0.15 \\
\text{s}_3 \quad 0.16 \\
\text{s}_4 \quad 0.19 \\
\text{s}_5 \quad 0.40 \\
\hline
\end{array}
```

Code length: 2.25 bit/symbol
Code efficiency: 0.955

**Huffman Coding** (1952)

```
\begin{array}{c}
\text{s}_1, \text{s}_2, \text{s}_3, \text{s}_4, \text{s}_5 \\
| \quad 0.60 \\
\text{s}_1, \text{s}_2, \text{s}_3 \quad 0.25 \\
\text{s}_1, \text{s}_2 \quad 0.16 \\
\text{s}_1 \quad 0.10 \\
\text{s}_2 \quad 0.15 \\
\text{s}_3, \text{s}_4 \quad 0.35 \\
\text{s}_3 \quad 0.16 \\
\text{s}_4 \quad 0.19 \\
\text{s}_5 \quad 0.40 \\
\hline
\end{array}
```

Code length: 2.20 bit/symbol
Code efficiency: 0.977
It can be shown that Huffman coding is optimal if we have to determine the obtaining alternative in a single instance. (No question/coding scheme has a smaller expected number of questions.)

Only if the obtaining alternative has to be determined in a sequence of (independent) situations, this scheme can be improved upon.

Idea: Process the sequence not instance by instance, but combine two, three or more consecutive instances and ask directly for the obtaining combination of alternatives.

Although this enlarges the question/coding scheme, the expected number of questions per identification is reduced (because each interrogation identifies the obtaining alternative for several situations).

However, the expected number of questions per identification cannot be made arbitrarily small. Shannon showed that there is a lower bound, namely the Shannon entropy.
Interpretation of Shannon Entropy

\[
P(s_1) = \frac{1}{2}, \quad P(s_2) = \frac{1}{4}, \quad P(s_3) = \frac{1}{8}, \quad P(s_4) = \frac{1}{16}, \quad P(s_5) = \frac{1}{16}
\]

Shannon entropy:
\[
- \sum_i P(s_i) \log_2 P(s_i) = 1.875 \text{ bit/symbol}
\]

If the probability distribution allows for a perfect Huffman code (code efficiency 1), the Shannon entropy can easily be interpreted as follows:

\[
- \sum_i P(s_i) \log_2 P(s_i) = \sum_i P(s_i) \cdot \log_2 \frac{1}{P(s_i)}
\]

In other words, it is the expected number of needed yes/no questions.

Perfect Question Scheme

Code length: 1.875 bit/symbol
Code efficiency: 1
Other Information-theoretic Evaluation Measures

Normalized Information Gain

Information gain is biased towards many-valued attributes.
Normalization removes / reduces this bias.

**Information Gain Ratio**  (Quinlan 1986 / 1993)

$$I_{gr}(C, A) = \frac{I_{\text{gain}}(C, A)}{H_A} = \frac{I_{\text{gain}}(C, A)}{- \sum_{j=1}^{n_A} p_j \log_2 p_j}$$

**Symmetric Information Gain Ratio**  (López de Mántaras 1991)

$$I_{sgr}^{(1)}(C, A) = \frac{I_{\text{gain}}(C, A)}{H_{AC}}$$

or

$$I_{sgr}^{(2)}(C, A) = \frac{I_{\text{gain}}(C, A)}{H_A + H_C}$$
Information gain is biased towards many-valued attributes, i.e., of two attributes having about the same information content it tends to select the one having more values.

The reasons are quantization effects caused by the finite number of example cases (due to which only a finite number of different probabilities can result in estimations) in connection with the following theorem:

Theorem: Let $A$, $B$, and $C$ be three attributes with finite domains and let their joint probability distribution be strictly positive, i.e., $\forall a \in \text{dom}(A): \forall b \in \text{dom}(B): \forall c \in \text{dom}(C): P(A = a, B = b, C = c) > 0$. Then

$$I_{\text{gain}}(C, AB) \geq I_{\text{gain}}(C, B),$$

with equality obtaining only if the attributes $C$ and $A$ are conditionally independent given $B$, i.e., if $P(C = c | A = a, B = b) = P(C = c | B = b)$.

(A detailed proof of this theorem can be found, for example, in [Borgelt and Kruse 2002], p. 311ff.)
A Statistical Evaluation Measure

$\chi^2$ Measure

Compresses the actual joint distribution with a hypothetical independent distribution.

Uses absolute comparison.

Can be interpreted as a difference measure.

$$\chi^2(C, A) = \sum_{i=1}^{n_C} \sum_{j=1}^{n_A} N_{..} \frac{(p_{i..}.j - p_{ij})^2}{p_{i..}p_{..j}}$$

Side remark: Information gain can also be interpreted as a difference measure.

$$I_{\text{gain}}(C, A) = \sum_{i=1}^{n_C} \sum_{j=1}^{n_A} p_{ij} \log_2 \frac{p_{ij}}{p_{i..}p_{..j}}$$
General Approach: Discretization

Preprocessing I

Form equally sized or equally populated intervals.

During the tree construction

Sort the example cases according to the attribute’s values.
Construct a binary symbolic attribute for every possible split (values: “≤ threshold” and “> threshold”).
Compute the evaluation measure for these binary attributes.
Possible improvements: Add a penalty depending on the number of splits.

Preprocessing II / Multisplits during tree construction

Build a decision tree using only the numeric attribute.
Flatten the tree to obtain a multi-interval discretization.
Induction

Weight the evaluation measure with the fraction of cases with known values.

Idea: The attribute provides information only if it is known.

Try to find a surrogate test attribute with similar properties (CART, Breiman et al. 1984)

Assign the case to all branches, weighted in each branch with the relative frequency of the corresponding attribute value (C4.5, Quinlan 1993).

Classification

Use the surrogate test attribute found during induction.

Follow all branches of the test attribute, weighted with their relative number of cases, aggregate the class distributions of all leaves reached, and assign the majority class of the aggregated class distribution.
Pruning serves the purpose

to simplify the tree (improve interpretability),
to avoid overfitting (improve generalization).

Basic ideas:
Replace “bad” branches (subtrees) by leaves.
Replace a subtree by its largest branch if it is better.

Common approaches:
Reduced error pruning
Pessimistic pruning
Confidence level pruning
Minimum description length pruning
Classify a set of new example cases with the decision tree. (These cases must not have been used for the induction!)

Determine the number of errors for all leaves.

The number of errors of a subtree is the sum of the errors of all of its leaves.

Determine the number of errors for leaves that replace subtrees.

If such a leaf leads to the same or fewer errors than the subtree, replace the subtree by the leaf.

If a subtree has been replaced, recompute the number of errors of the subtrees it is part of.

**Advantage:** Very good pruning, effective avoidance of overfitting.

**Disadvantage:** Additional example cases needed.
Pessimistic Pruning

Classify a set of example cases with the decision tree. (These cases may or may not have been used for the induction.)

Determine the number of errors for all leaves and increase this number by a fixed, user-specified amount $r$.

The number of errors of a subtree is the sum of the errors of all of its leaves.

Determine the number of errors for leaves that replace subtrees (also increased by $r$).

If such a leaf leads to the same or fewer errors than the subtree, replace the subtree by the leaf and recompute subtree errors.

**Advantage:** No additional example cases needed.

**Disadvantage:** Number of cases in a leaf has no influence.
Like pessimistic pruning, but the number of errors is computed as follows:

1. See classification in a leaf as a Bernoulli experiment (error / no error).

2. Estimate an interval for the error probability based on a user-specified confidence level \( \alpha \).
   (use approximation of the binomial distribution by a normal distribution)

3. Increase error number to the upper level of the confidence interval times the number of cases assigned to the leaf.

4. Formal problem: Classification is not a random experiment.

**Advantage:** No additional example cases needed, good pruning.

**Disadvantage:** Statistically dubious foundation.
Pruning a Decision Tree: A Simple Example

Pessimistic Pruning with $r = 0.8$ and $r = 0.4$: 

\[ c_1: 13, \ c_2: 7 \]

- **Leaf:** 7.0 errors
- **$r = 0.8$:** 7.8 errors (prune subtree)
- **$r = 0.4$:** 7.4 errors (keep subtree)

\[ c_1: 5, \ c_2: 2 \]
- 2.8 errors
- 2.4 errors

\[ c_1: 6, \ c_2: 2 \]
- 2.8 errors
- 2.4 errors

\[ c_1: 2, \ c_2: 3 \]
- 2.8 errors
- 2.4 errors

**Total:** 6.0 errors

\[ r = 0.8: \ 8.4 \text{ errors} \]
\[ r = 0.4: \ 7.2 \text{ errors} \]
A decision tree for the Iris data
(induced with information gain ratio, unpruned)
A decision tree for the Iris data
(pruned with confidence level pruning, $\alpha = 0.8$, and pessimistic pruning, $r = 2$)

Left: 7 instead of 11 nodes, 4 instead of 2 misclassifications.
Right: 5 instead of 11 nodes, 6 instead of 2 misclassifications.
The right tree is “minimal” for the three classes.
Decision Trees are Classifiers with Tree Structure

- Inner node: Test of a descriptive attribute
- Leaf node: Assignment of a class

Induction of Decision Trees from Data
(Top-Down Induction of Decision Trees, TDIDT)

- Divide and conquer approach / recursive descent
- Greedy selection of the test attributes
  Attributes are selected based on an evaluation measure,
  e.g. information gain, $\chi^2$ measure
- Recommended: Pruning of the decision tree
General method to evaluate / predict the performance of classifiers.

Serves the purpose to estimate the error rate on new example cases.

Procedure of cross validation:

1. Split the given data set into \( n \) so-called \textit{folds} of equal size (\( n \)-fold cross validation).

2. Combine \( n - 1 \) folds into a training data set, build a classifier, and test it on the \( n \)-th fold.

3. Do this for all \( n \) possible selections of \( n - 1 \) folds and average the error rates.

Special case: Leave-1-out cross validation.
(use as many folds as there are example cases)

Final classifier is learned from the full data set.
Support Vector Machines
**Training data:**  Expression profiles of patients with known diagnosis

The known diagnosis gives us a structure within the data, which we want to generalize for future data.

**Learning/Training:** Derive a decision rule from the training data which separates the two classes.

**Ability for generalization:** How useful is the decision rule when it comes to diagnosing patients in the future?

**Aim:** Find a decision rule with high ability for generalization!
Given: \( X = \{x_i, y_i\}_{i=1}^n \), training data of patients with known diagnosis consists of:

\[
\begin{align*}
    x_i &\in \mathbb{R}^g \text{ (points, expression profiles)} \\
y_i &\in \{+1, -1\} \text{ (classes, 2 kinds of cancer)}
\end{align*}
\]

Decision function:

\[
f_X : \mathbb{R}^g \rightarrow \{+1, -1\}
\]

\[
\text{diagnosis} = f_X(\text{new patient})
\]
Underfitting / Overfitting

- **too simple**
- **too complex**

- negative example
- positive example
- new patient

tradeoff
Begin with linear separation and increase the complexity in a second step with a kernel function.

A separating hyperplane is defined by

- a normal vector $w$
- an offset $b$

Hyperplane $H = \{x | \langle w, x \rangle + b = 0 \}$

$\langle \cdot, \cdot \rangle$ is called the inner product or scalar product.
**Training:** Choose $w$ and $b$ in such a way that the hyperplane separates the training data.

**Prediction:** Which side of the hyperplane is the new point located on?

Points on the side that the normal vector points at are diagnosed as **POSITIVE**.

Points on the other side are diagnosed as **NEGATIVE**.
Motivation

Origin in Statistical Learning Theory; class of optimal classifiers
Core problem of Statistical Learning Theory: Ability for generalization. When does a low training error lead to a low real error?

**Binary Class Problem:**
Classification $\equiv$ mapping function $f(x, u) : x \rightarrow y \in \{+1, -1\}$
$x$: sample from one of the two classes
$u$: parameter vector of the classifier

Learning sample with $l$ observations $x_1, x_2, \ldots, x_l$
along with their class affiliation $y_1, y_2, \ldots, y_l$
$\rightarrow$ the **empirical risk** (error rate) for a given training dataset:

$$R_{emp}(u) = \frac{1}{2l} \sum_{i=1}^{l} |y_i - f(x_i, u)| \in [0, 1]$$

A lot of classifiers do minimize the empirical risk, e.g. Neural Networks.
**Motivation**

Expected value of classification error (expected risk):

\[
R(u) = E\{R_{test}(u)\} = E\left\{\frac{1}{2}|y - f(x, u)|\right\} = \int \frac{1}{2}|y - f(x, u)| p(x, y) \, dx \, dy
\]

\(p(x, y)\): Distribution density of all possible samples \(x\) along with their class affiliation \(y\) (Can’t evaluate this expression directly as \(p(x, y)\) is not available.)

**Optimal** sample classification:
Search for deterministic mapping function \(f(x, u): x \rightarrow y \in \{+1, -1\}\) that minimizes the expected risk.

Core question of sample classification:

How close do we get to the real error after we saw \(l\) training samples? How well can we estimate the real risk \(R(u)\) from the empirical risk \(R_{emp}(u)\)?

(Structural Risk Minimization instead of Empirical Risk Minimization)

The answer is given by Learning Theory of Vapnik-Chervonenkis \(\rightarrow\) SVMs
Previous solution:

General hyperplane: \( wx + b = 0 \)

Classification: \( \text{sgn}(wx + b) \)

Training, e.g. by perceptron-algorithm
(iterative learning, correction after every misclassification; no unique solution)
Task: Find values $\vec{x} = (x_1, \ldots, x_m)$ such that $f(\vec{x}) = f(x_1, \ldots, x_m)$ is optimal.

Often feasible approach:

A necessary condition for a (local) optimum (maximum or minimum) is that the partial derivatives w. r. t. the parameters vanish (Pierre Fermat).

Therefore: (Try to) solve the equation system that results from setting all partial derivatives w. r. t. the parameters equal to zero.

Example task: Minimize $f(x, y) = x^2 + y^2 + xy - 4x - 5y$.

Solution procedure:

Take the partial derivatives of the objective function and set them to zero:

$$\frac{\partial f}{\partial x} = 2x + y - 4 = 0,$$
$$\frac{\partial f}{\partial y} = 2y + x - 5 = 0.$$

Solve the resulting (here: linear) equation system: $x = 1, y = 2$. 

Often a function has to be optimized subject to certain constraints.

**Here:** restriction to *k* equality constraints \( C_i(\vec{x}) = 0, \ i = 1, \ldots, k. \)

**Note:** the equality constraints describe a subspace of the domain of the function.

**Problem** of optimization with constraints:

The gradient of the objective function \( f \) may vanish outside the constrained subspace, leading to an unacceptable solution (violating the constraints).

At an optimum *in the constrained subspace* the derivatives need not vanish.

One way to handle this problem are **generalized coordinates**:

Exploit the dependence between the parameters specified in the constraints to express some parameters in terms of the others and thus reduce the set \( \vec{x} \) to a set \( \vec{x}' \) of independent parameters (generalized coordinates).

Problem: Can be clumsy and cumbersome, if possible at all, because the form of the constraints may not allow for expressing some parameters as proper functions of the others.
Contour Lines: Given a function $f : \mathbb{R}^2 \rightarrow \mathbb{R}$, the contour plot is obtained by drawing the contour sets for equidistant levels, i.e., plot the following sets of points:

$$M_{kc} = \{(x_1, x_2) \in \mathbb{R}^2 \mid f(x_1, x_2) = kc\}$$

for $k \in \mathbb{N}$ and fixed $c \in \mathbb{R}_{\geq 0}$

Example: $f(x_1, x_2) = x_1^2 + x_2^2$
The gradient of a function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ consists of the vector of its partial derivatives w.r.t. the arguments:

$$\nabla_{\vec{x}} f = \left( \frac{\partial f}{\partial x_1}, \ldots, \frac{\partial f}{\partial x_n} \right)^\top$$

The gradient evaluated at a point $\vec{x}^*$, written as

$$\nabla_{\vec{x}} f \big|_{\vec{x}^*} = \left( \frac{\partial f}{\partial x_1} \big|_{x_1^*}, \ldots, \frac{\partial f}{\partial x_n} \big|_{x_n^*} \right)^\top,$$

points into the direction of largest increase of $f$.

Formally, the gradient of a function with domain $\mathbb{R}^n$ has $n$ dimensions although it is often depicted as an $n + 1$-dimensional vector.
Gradient Field of a Function: Examples

\[ f_1(x_1, x_2) = x_1^2 + x_2^2 \]
\[ \nabla \vec{x} f_1 = \begin{pmatrix} 2x_1 \\ 2x_2 \end{pmatrix} \]

\[ f_2(x_1, x_2) = x_1 + x_2 - 1 \]
\[ \nabla \vec{x} f_2 = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \]
Problem: If the global optimum of $f$ lies outside the feasible region, the gradient does not vanish at the constrained optimum $\bar{x}^*$. 

Which criteria do hold at the constrained optimum?

Assume we move $\bar{x}^*$ throughout the feasible region to find the optimum “manually”. If we cross a contour line of $f$, the crossing point cannot be an optimum: because crossing a contour line means descending or ascending.

However, if we touch a contour line we have found an optimum because stepping backward or forward will increase (or decrease) the value.

At the “touching point” $\bar{x}^*$ the gradient of $f$ and the gradient of $g$ are parallel.

\[ \nabla f = \lambda \nabla g \]

We only need both gradients to be parallel. Since they can have opposite directions and different lengths $\lambda$ is used to rescale $\nabla g$. 
**Task:** Minimize \( f(x_1, x_2) = x_1^2 + x_2^2 \) subject to \( g: x + y = 1 \).

**Crossing a contour line:** Point 1 cannot be a constrained minimum because \( \nabla f \) has a non-zero component in the constrained space. Walking in opposite direction to this component can further decrease \( f \).

**Touching a contour line:** Point 2 is a constrained minimum: both gradients are parallel, hence there is no component of \( \nabla f \) in the constrained space that might lead us to a lower value of \( f \).
Therefore, at the constrained optimum $\vec{x}^\ast$ we require:

$$\nabla f(\vec{x}^\ast) = \lambda \nabla g(\vec{x}^\ast) \quad \text{and} \quad g(\vec{x}^\ast) = 0$$

More compact representation:

$$L(\vec{x}, \lambda) = f(\vec{x}) - \lambda g(\vec{x}) \quad \text{and} \quad \nabla L = 0$$

Taking the partial derivatives reveals the initial conditions:

$$\frac{\partial}{\partial \vec{x}} L(\vec{x}, \lambda) = \nabla f(\vec{x}) - \lambda \nabla g(\vec{x}) = 0$$

$$\nabla f(\vec{x}) = \lambda \nabla g(\vec{x})$$

$$\frac{\partial}{\partial \lambda} L(\vec{x}, \lambda) = g(\vec{x}) = 0$$

The negative sign in the Lagrange function $L$ can be incorporated into $\lambda$, i.e. we will from now on replace it by a positive sign.
Example task: Minimize $f(x, y) = x^2 + y^2$ subject to $x + y = 1$.

Solution procedure:

Rewrite the constraint, so that one side gets zero: $x + y - 1 = 0$.

Construct the Lagrange function by incorporating the constraint into the objective function with a Lagrange multiplier $\lambda$:

$$L(x, y, \lambda) = x^2 + y^2 + \lambda(x + y - 1).$$

Take the partial derivatives of the Lagrange function and set them to zero (necessary conditions for a minimum):

$$\frac{\partial L}{\partial x} = 2x + \lambda = 0, \quad \frac{\partial L}{\partial y} = 2y + \lambda = 0, \quad \frac{\partial L}{\partial \lambda} = x + y - 1 = 0.$$

Solve the resulting (here: linear) equation system:

$$\lambda = -1, \quad x = y = \frac{1}{2}.$$
Let $\mathbf{x}^*$ be a (local) optimum of $f(\mathbf{x})$ in the constrained subspace. Then:

The gradient $\nabla_{\mathbf{x}} f(\mathbf{x}^*)$, if it does not vanish, must be perpendicular to the constrained subspace. (If $\nabla_{\mathbf{x}} f(\mathbf{x}^*)$ had a component in the constrained subspace, $\mathbf{x}^*$ would not be a (local) optimum in this subspace.)

The gradients $\nabla_{\mathbf{x}} g_j(\mathbf{x}^*)$, $1 \leq j \leq k$, must all be perpendicular to the constrained subspace, because they are constant, namely 0, in this subspace. Together they span the subspace perpendicular to the constrained subspace.

Therefore it must be possible to find values $\lambda_j$, $1 \leq j \leq k$, such that

$$\nabla_{\mathbf{x}} f(\mathbf{x}^*) + \sum_{j=1}^{s} \lambda_j \nabla_{\mathbf{x}} g_j(\mathbf{x}^*) = 0.$$

If the constraints (and thus their gradients) are linearly independent, the values $\lambda_j$ are uniquely determined. This equation can be used to compensate the gradient of $f(\mathbf{x}^*)$ so that it vanishes at $\mathbf{x}^*$. 

As a consequence of these insights we obtain the

**Method of Lagrange Multipliers:**

**Given:**
- A function \( f(\vec{x}) \), which is to be optimized,
- \( k \) equality constraints \( g_j(\vec{x}) = 0, \ 1 \leq j \leq k \).

**Procedure:**

Construct the so-called **Lagrange function** by incorporating the equality constraints \( g_i, \ i = 1, \ldots, k \), with (unknown) **Lagrange multipliers** \( \lambda_i \):

\[
L(\vec{x}, \lambda_1, \ldots, \lambda_k) = f(\vec{x}) + \sum_{i=1}^{k} \lambda_i g_i(\vec{x}).
\]

Set the partial derivatives of the Lagrange function equal to zero:

\[
\frac{\partial L}{\partial x_1} = 0, \quad \ldots, \quad \frac{\partial L}{\partial x_m} = 0, \quad \frac{\partial L}{\partial \lambda_1} = 0, \quad \ldots, \quad \frac{\partial L}{\partial \lambda_k} = 0.
\]

(Try to) solve the resulting equation system.
**Example task:** Minimize \( f(x, y) = x^2 + y^2 \) subject to \( x + y = 1 \).

The unconstrained minimum is not in the constrained subspace, and at the minimum in the constrained subspace the gradient does not vanish.
Example task: Minimize \( f(x, y) = x^2 + y^2 \) subject to \( x + y = 1 \).

\[ C(x, y) = x + y - 1 \]

\[ L(x, y, -1) = x^2 + y^2 - (x + y - 1) \]

minimum \( \vec{p}_1 = (\frac{1}{2}, \frac{1}{2}) \)

The gradient of the constraint is perpendicular to the constrained subspace. The (unconstrained) minimum of the Lagrange function \( L(x, y, \lambda) \) is the minimum of the objective function \( f(x, y) \) in the constrained subspace.
Example task: Find the side lengths $x$, $y$, $z$ of a box with maximum volume for a given area $S$ of the surface.

Formally: Maximize $f(x, y, z) = xyz$
subject to $2xy + 2xz + 2yz = S$.

Solution procedure:

The constraint is $C(x, y, z) = 2xy + 2xz + 2yz - S = 0$.

The Lagrange function is

$$L(x, y, z, \lambda) = xyz + \lambda(2xy + 2xz + 2yz - S).$$

Taking the partial derivatives yields (in addition to the constraint):

$$\frac{\partial L}{\partial x} = yz + 2\lambda(y+z) = 0, \quad \frac{\partial L}{\partial y} = xz + 2\lambda(x+z) = 0, \quad \frac{\partial L}{\partial y} = xy + 2\lambda(x+y) = 0.$$ 

The solution is: $\lambda = -\frac{1}{4} \sqrt{\frac{S}{6}}$, $x = y = z = \sqrt{\frac{S}{6}}$ (i.e., the box is a cube).
Observations:

Due to the representation of the gradient of $f(\vec{x})$ at a local optimum $\vec{x}^*$ in the constrained subspace (see above) the gradient of $L$ w.r.t. $\vec{x}$ vanishes at $\vec{x}^*$.

→ The standard approach works again!

If the constraints are satisfied, the additional terms have no influence.
→ The original task is not modified (same objective function).

Taking the partial derivative w.r.t. a Lagrange multiplier reproduces the corresponding equality constraint:

$$\forall j; 1 \leq j \leq k : \frac{\partial}{\partial \lambda_j} L(\vec{x}, \lambda_1, \ldots, \lambda_k) = C_j(\vec{x}),$$

→ Constraints enter the equation system to solve in a natural way.

Remark:

Inequality constraints can be handled with the **Kuhn–Tucker theory**.
Which hyperplane is the best - and why?
No exact cut, but a …
Separate the training data with maximal separation margin.
Separate the training data with maximal separation margin

Try linear separation, but accept errors:

Penalty for errors: Distance to hyperplane times error weight $C$
SVMs for linearly separable classes

With SVMs we are searching for a separating hyperplane with maximal margin. *Optimum:* The hyperplane with the highest $2\delta$ of all possible separating hyperplanes.

This is intuitively meaningful (At constant intra-class scattering, the confidence of right classification is growing with increasing inter-class distance)

SVMs are theoretically justified by Statistical Learning Theory.
Large-Margin Classifier: Separation line 2 is better than 1
SVMs for linearly separable classes

\[ wx + b = +1 \]
\[ wx + b = -1 \]

Training samples are classified correctly, if:
\[ y_i (wx_i + b) > 0 \]
Invariance of this expression towards a positive scaling leads to:
\[ y_i (wx_i + b) \geq 1 \]
with canonical hyperplanes:
\[
\begin{cases}
wx_i + b = +1; \text{(class with } y_i = +1) \\
wx_i + b = -1; \text{(class with } y_i = -1) 
\end{cases}
\]

The distance between the canonical hyperplanes results from projecting \( x_1 - x_2 \) to the unit length normal vector \( \frac{w}{||w||} \):
\[
2\delta = \frac{2}{||w||}; \quad \text{d.h. } \delta = \frac{1}{||w||}
\]
\[ \rightarrow \text{maximizing } \delta \equiv \text{minimizing } ||w||^2 \]
Optimal separating plane by minimizing a quadratic function to linear constraints:

**Primal Optimization Problem:**

\[
\text{minimize: } J(w, b) = \frac{1}{2}||w||^2 \\
to the constraints } \forall i \ [y_i(wx_i + b) \geq 1], \ i = 1, 2, \ldots, l
\]

Introducing a Lagrange-Function:

\[
L(w, b, \alpha) = \frac{1}{2}||w||^2 - \sum_{i=1}^{l} \alpha_i[y_i(wx_i + b) - 1]; \ \alpha_i \geq 0
\]

leads to the *dual problem*:

maximize \(L(w, b, \alpha)\) with respect to \(\alpha\), under the constraints:

\[
\frac{\partial L(w,b,\alpha)}{\partial w} = 0 \implies w = \sum_{i=1}^{l} \alpha_iy_ix_i
\]

\[
\frac{\partial L(w,b,\alpha)}{\partial b} = 0 \implies \sum_{i=1}^{l} \alpha_i y_i = 0
\]
Insert this terms in $L(w, b, \alpha)$:

$$L(w, b, \alpha) = \frac{1}{2}||w||^2 - \sum_{i=1}^{l} \alpha_i[y_i(wx_i + b) - 1]$$

$$= \frac{1}{2}w \cdot w - w \cdot \sum_{i=1}^{l} \alpha_i y_i x_i - b \cdot \sum_{i=1}^{l} \alpha_i y_i + \sum_{i=1}^{l} \alpha_i$$

$$= \frac{1}{2}w \cdot w - w \cdot w + \sum_{i=1}^{l} \alpha_i$$

$$= \frac{1}{2}w \cdot w + \sum_{i=1}^{l} \alpha_i$$

$$= -\frac{1}{2} \sum_{i=1}^{l} \sum_{j=1}^{l} y_i y_j \alpha_i \alpha_j x_i x_j + \sum_{i=1}^{l} \alpha_i$$
Dual Optimization Problem:

maximize: \( L'(\alpha) = \sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i=1}^{l} \sum_{j=1}^{l} y_i y_j \alpha_i \alpha_j x_i x_j \)

to the constraints \( \alpha_i \geq 0 \) and \( \sum_{i=1}^{l} y_i \alpha_i = 0 \)

This optimization problem can be solved numerically with the help of standard quadratic programming techniques.
**Solution** of the optimization problem:

\[
\begin{align*}
    w^* &= \sum_{i=1}^{l} \alpha_i y_i x_i = \sum_{x_i \in SV} \alpha_i y_i x_i \\
    b^* &= -\frac{1}{2} \cdot w^* \cdot (x_p + x_m) \\
    &\text{for arbitrary } x_p \in SV, \ y_p = +1, \ \text{und } x_m \in SV, \ y_m = -1
\end{align*}
\]

where

\[
SV = \{ x_i \mid \alpha_i > 0, \ i = 1, 2, \ldots, l \}
\]

is the set of all support vectors.

**Classification rule:**

\[
\text{sgn}(w^* x + b^*) = \text{sgn}\left[ (\sum_{x_i \in SV} \alpha_i y_i x_i)x + b^* \right]
\]

The classification only depends on the support vectors!
SVMs for linearly separable classes

Example: Support Vectors
SVMs for linearly separable classes

Example: class +1 contains $x_1 = (0, 0)$ and $x_2 = (1, 0)$; class -1 contains $x_3 = (2, 0)$ and $x_4 = (0, 2)$
The Dual Optimization Problem is:

\[
\text{maximize: } L'(\alpha) = (\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4) - \frac{1}{2}(\alpha_2^2 - 4\alpha_2\alpha_3 + 4\alpha_3^2 + 4\alpha_4^2)
\]
to the constraints \(\alpha_i \geq 0\) and \(\alpha_1 + \alpha_2 - \alpha_3 - \alpha_4 = 0\)

Solution:

\[
\alpha_1 = 0, \quad \alpha_2 = 1, \quad \alpha_3 = \frac{3}{4}, \quad \alpha_4 = \frac{1}{4}
\]

\(SV = \{(1,0), (2,0), (0,2)\}\)

\[
w^* = 1 \cdot (1,0) - \frac{3}{4} \cdot (2,0) - \frac{1}{4} \cdot (0,2) = (-\frac{1}{2}, -\frac{1}{2})
\]

\[
b^* = -\frac{1}{2} \cdot (-\frac{1}{2}, -\frac{1}{2}) \cdot ((1,0) + (2,0)) = \frac{3}{4}
\]

Optimal separation line: \(x + y = \frac{3}{2}\)
Observations:
For the Support Vectors holds: $\alpha_i > 0$
For all training samples outside the margin holds: $\alpha_i = 0$
Support Vectors form a *sparse* representation of the sample; They are sufficient for classification.
The solution is the global optima and unique
The optimization procedure only requires scalar products $x_ix_j$
SVMs for non-linearly separable classes

In this example there is no separating line such as \( \forall i \ [y_i(wx_i + b) \geq 1] \)

Three possible cases:

A) Vectors beyond the margin, which are correctly classified, i.e.
\[ y_i(wx_i + b) \geq 1 \]

B) Vectors within the margin, which are correctly classified, i.e.
\[ 0 \leq y_i(wx_i + b) < 1 \]

C) Vectors that are not correctly classified, i.e.
\[ y_i(wx_i + b) < 0 \]

All three cases can be interpreted as: \( y_i(wx_i + b) \geq 1 - \xi_i \)

A) \( \xi_i = 0 \)

B) \( 0 < \xi_i \leq 1 \)

C) \( \xi_i > 1 \)
Motivation for generalization:

Previous approach gives no solution for classes that are non-lin. separable.

Improvement of the generalization on outliers within the margin

**Soft-Margin SVM:** Introduce “slack”-Variables
Penalty for outliers via “slack”-Variables

**Primale Optimization Problem:**

minimize:  \( J(w, b, \xi) = \frac{1}{2}||w||^2 + C \sum_{i=1}^{l} \xi_i \)

to the constraints \( \forall i \ [y_i(wx_i + b) \geq 1 - \xi_i, \ \xi_i \geq 0] \)

**Dual Optimization Problem:**

maximize:  \( L'(\alpha) = \sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i=1}^{l} \sum_{j=1}^{l} y_i y_j \alpha_i \alpha_j x_i x_j \)

to the constraints 0 \( \leq \alpha_i \leq C \) and  \( \sum_{i=1}^{l} y_i \alpha_i = 0 \)

(Neither slack-Variables nor Lagrange-Multiplier occur in the dual optimization problem.)

The only difference compared to the linear separable case: Constant \( C \) in the constraints.
SVMs for non-linearly separable classes

Solution of the optimization problem:

\[ w^* = \sum_{i=1}^{l} \alpha_i y_i x_i = \sum_{x_i \in SV} \alpha_i y_i x_i \]

\[ b^* = y_k(1 - \xi_k) - w^* x_k; \quad k = \arg \max_i \alpha_i \]

where

\[ SV = \{x_i \mid \alpha_i > 0, \ i = 1, 2, \ldots, l\} \]

describes the set of all Support Vectors.
SVMs for non-linearly separable classes

Example: non-linearly separable classes
Non-linear SVMs

Non-linear class boundaries → low precision

Example: Transformation $\Psi(x) = (x, x^2) \rightarrow C_1$ and $C_2$ linearly separable

\[ \circ \quad \circ \]
\[ \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \]
\[ \rightarrow \]
\[ \circ \quad \circ \quad \circ \quad \circ \]
\[ \circ \quad \circ \quad \circ \quad \circ \]

Idea:
Transformation of attributes $x \in \mathbb{R}^n$ in a higher dimensional space $\mathbb{R}^m$, $m > n$ by

$\Psi : \mathbb{R}^n \rightarrow \mathbb{R}^m$

and search for an optimal linear separating hyperplane in this space.

Transformation $\Psi$ increases linear separability.

Separating hyperplane in $\mathbb{R}^m \equiv$ non-linear separating plane in $\mathbb{R}^n$
Non-linear SVMs

Problem: High dimensionality of the attribute space \( \mathbb{R}^m \)
E.g. Polynomials of \( p \)-th degree over \( \mathbb{R}^n \rightarrow \mathbb{R}^m \), \( m = O(n^p) \)

Trick with kernel function:
Originally in \( \mathbb{R}^n \): only scalar products \( x_ix_j \) required
new in \( \mathbb{R}^m \): only scalar products \( \Psi(x_i)\Psi(x_j) \) required

Solution
No need to compute \( \Psi(x_i)\Psi(x_j) \), but express them at reduced complexity with the kernel function

\[
K(x_i, x_j) = \Psi(x_i)\Psi(x_j)
\]
Example: For the transformation $\Psi : \mathbb{R}^2 \rightarrow \mathbb{R}^6$

$$\Psi((y_1, y_2)) = (y_1^2, y_2^2, \sqrt{2}y_1, \sqrt{2}y_2, \sqrt{2}y_1y_2, 1)$$

the kernel function computes

$$K(x_i, x_j) = (x_i x_j + 1)^2$$

$$= ((y_{i1}, y_{i2}) \cdot (y_{j1}, y_{j2}) + 1)^2$$

$$= (y_{i1}y_{j1} + y_{i2}y_{j2} + 1)^2$$

$$= (y_{i1}^2, y_{i2}^2, \sqrt{2}y_{i1}, \sqrt{2}y_{i2}, \sqrt{2}y_{i1}y_{i2}, 1) \cdot (y_{j1}^2, y_{j2}^2, \sqrt{2}y_{j1}, \sqrt{2}y_{j2}, \sqrt{2}y_{j1}y_{j2}, 1)$$

$$= \Psi(x_i)\Psi(x_j)$$

the scalar product in the new attribute space $\mathbb{R}^6$
Non-linear SVMs

Example: \( \Psi : \mathbb{R}^2 \rightarrow \mathbb{R}^3 \)

\[
\Psi((y_1, y_2)) = (y_1^2, \sqrt{2}y_1y_2, y_2^2)
\]

The kernel function

\[
K(x_i, x_j) = (x_ix_j)^2 = \Psi(x_i)\Psi(x_j)
\]

computes the scalar product in the new attribute space \( \mathbb{R}^3 \). It is possible to compute the scalar product of \( \Psi(x_i) \) and \( \Psi(x_j) \) without applying the function \( \Psi \).
Nonlinear SVMs

Commonly used kernel functions:

Polynomial-Kernel: \[ K(x_i, x_j) = (x_i x_j)^d \]

Gauss-Kernel: \[ K(x_i, x_j) = e^{-\frac{||x_i - x_j||^2}{c}} \]

Sigmoid-Kernel: \[ K(x_i, x_j) = \tanh(\beta_1 x_i x_j + \beta_2) \]

Linear combination of valid kernels → new kernel functions

We do not need to know what the new attribute space \( \mathbb{R}^m \) looks like. The only thing we need is the kernel function as a measure for similarity.
Non-linear SVMs

Example: Gauss-Kernel \((c = 1)\). The Support Vectors are tagged by an extra circle.
Non-linear SVMs

Example: Gauss-Kernel \((c = 1)\) for Soft-Margin SVM.
Final Remarks

Advantages of SVMs:
According to current knowledge SVMs yield very good classification results; in some tasks they are considered to be the top-performer.
Sparse representation of the solution by Support Vectors
Easily practicable: few parameters, no need for a-priori-knowledge
Geometrically intuitive operation
Theoretical statements about results: global optima, ability for generalization

Disadvantages of SVMs
Learning process is slow and in need of intense memory
“Tuning SVMs remains a black art: selecting a specific kernel and parameters is usually done in a try-and-see manner”
List of SVM-implementations at

Deep Learning
Problem: Object recognition in images

Imagenet Large Scale Visual Recognition Challenge (LSVRC) since 2010 identify 200 different classes of objects (chair, table, person, bike, ...)
images with approx. 500 × 400px, 3 color channels (RGB)
nearal network with approx. 600’000 neurons in the first layer
200 neurons in output layer
Motivation: No matter where on the image the object is, it should be recognized

Idea: Use the same features on the whole image

Implementation: Filter / Kernel are applied to every part of the image, sharing weights

Parameter: Number of filters, degree of overlapping
Convolution

Feature transformation
Move a filter over features and look at the filtered features
Multiply original feature and filter and summarize
Original space: 5x5
filter size: 3x3
new feature size: 3x3
feature space becomes smaller

Feature transformation
Move a filter over features and look at the filtered features
Consider area according to the filter’s size
Max pooling: Choose maximal value
Mean pooling: Calculate mean value
feature space becomes smaller
